

## PROJECT DOCUMENTATION:

### OBJECTIVE:

Currently the city of Buffalo receives reports from the Crime Lab in Albany in the form of hotspot maps and regular daily crime forecasting reports. The current system is not automated and requires human intervention to produce report.

This model has the objective of predicting crime numbers, then predict time and location autonomously with the goal of helping police departments introduce micro improvement that could have an impact in better allocating resources and improve response time.

### CONTEXT:

Buffalo is the second largest city in New York state with population estimate of 255,284, with median household income of \$37,354, and per capita income of \$24,40. The city of Buffalo's civilian labor force total is 59.8% of the total population and (Bureau, 2021).

According to city-data.com Crime in Buffalo is 450 per 100,000 , 1.7 times greater than the US average and higher than 93.9% of U.S. cities (City\_data, 2021). Compared to neighboring towns and cities, Buffalo has at least double the crime rate of the closest city/town.

Labor data indicates that early in the 1990's Buffalo started witnessing higher than usual unemployment rate as well as crime rate, the data also showed a consistent shrinkage of the labor pool , indicating a correlation between crime and employment. (Ajimotokin, 2015) establishes a clear correlation between crime and unemployment as well as the number of police officer and crime.

### THE PROBLEM:

How to forecast and predict crime in buffalo?

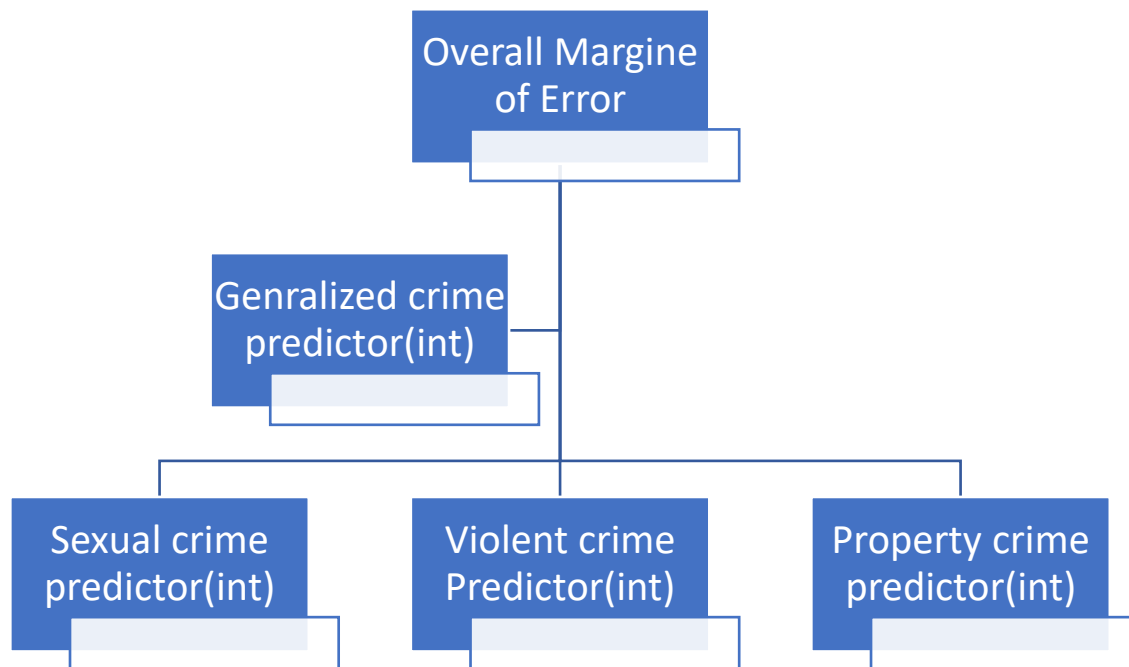

The hurdle around forecasting and predicting crime is the large number of variables that contribute to individuals committing crime. Yet, for the purpose of making a functioning and adequate predictor the use of variables should be broken and too many steps. I concluded that the first step is to build a generalized predictor based on employment data from New York State, this predictor will act as the guiding predictor other micro predictors.

### DESIGN:

The relationship between all predictors is going to work as cross-referencing system, where the generalized predictor will predict crime total and micro predictors will predict subsets of crimes such as sexual crimes, violent crimes, and property crimes. After fine tuning all the parameters for all four predictors we can proceed to work on establishing a predictor that could use the input from all four predictors to predict locations and times of where and when a crime might happen.

it is true that the three micro predictors that are concerned in generating numbers will output different numbers that might not align with the generalized predictor ,this issue could be perceived as a weakness or as strength ,in my opinion it is going to be strength Because we will be using their wisdom of crowds to establish better predictions as well as better margin of error to fine tune the overarching problem.

The following is a schema of the system:

#### CONSTRAINTS:

There are many constraints facing this model the first is government reporting ,police department's tend to report every incident in a sheet where it needs to be aggregated in order for better clarity and understanding of the data as well as generating numerical predictions. The reporting Takes the form of incident reporting meaning every incident it is reported individually and not aggregated to a daily total or monthly total.

| nt_id | case_number | incident_datetime         | incident_type_primary | incident_description                              | clearance_type | address_1                  | address_2 | city    | state | ... | location               | hour_of |

16 columns

(Data.gov, 2021)

Meanwhile employment data as reported by New York State all monthly basis , in order for the data to be used as exogenous variables to support the predictors crime data must be aggregated to monthly totals.

|   | Area        | Year | Month | Labor Force | Employed | Unemployed | Unemployment Rate |
|---|-------------|------|-------|-------------|----------|------------|-------------------|
| 0 | Albany City | 2021 | 1     | 46,800      | 43,100   | 3,700      | 7.9               |
| 1 | Albany City | 2020 | 12    | 47,200      | 43,500   | 3,700      | 7.8               |
| 2 | Albany City | 2020 | 11    | 47,400      | 43,800   | 3,600      | 7.7               |
| 3 | Albany City | 2020 | 10    | 47,200      | 43,500   | 3,800      | 8.0               |
| 4 | Albany City | 2020 | 9     | 47,200      | 43,200   | 3,900      | 8.4               |

Data source: (NYS, n.d.)

## DATA WRANGLING:

### Crime Data:

As mentioned above we needed to transform the data from an individual reporting to monthly reporting.

we first start by dropping unwanted columns ,in this case it is almost every column aside from the incident type and the date, we then Unify incident types into three distinct categories sexual, property, and violent .Once the and certain types unified we add a new column corresponding to incidents with number 1 to help aggregate the incidents to a total number. This could have been easier if the SQL API corresponding with New York State reporting worked, but after many tries I concluded that it was easier to manipulate the data on my own.

|   | incident_datetime      | incident_type_primary | hour_of_day | day_of_week |
|---|------------------------|-----------------------|-------------|-------------|
| 0 | 01/05/2020 01:30:00 AM | LARCENY/THEFT         | 2           | SUNDAY      |
| 1 | 01/05/2020 02:07:00 AM | MURDER                | 2           | SUNDAY      |
| 2 | 01/04/2020 11:00:48 PM | ASSAULT               | 2           | SUNDAY      |
| 3 | 01/05/2020 03:57:41 AM | ROBBERY               | 20          | SATURDAY    |
| 4 | 01/05/2020 04:00:00 AM | ASSAULT               | 4           | SUNDAY      |

we now have the data in the following form: date, incident type, hour, day, count .

|                     | type    | hour | day      | count |
|---------------------|---------|------|----------|-------|
| date                |         |      |          |       |
| 2020-01-05 01:30:00 | prperty | 2    | sunday   | 1     |
| 2020-01-05 02:07:00 | violent | 2    | sunday   | 1     |
| 2020-01-04 23:00:48 | violent | 2    | sunday   | 1     |
| 2020-01-05 03:57:41 | prperty | 20   | saturday | 1     |
| 2020-01-05 04:00:00 | violent | 4    | sunday   | 1     |

We then aggregate every single type on its own forming a data frame for the type indexed with the date column:

|      | date       | violent |
|------|------------|---------|
| 860  | 2005-06-30 | 2       |
| 957  | 2013-07-31 | 482     |
| 942  | 2012-04-30 | 384     |
| 888  | 2007-10-31 | 571     |
| 723  | 1994-01-31 | 0       |
| 865  | 2005-11-30 | 5       |
| 752  | 1996-06-30 | 0       |
| 952  | 2013-02-28 | 359     |
| 819  | 2002-01-31 | 2       |
| 945  | 2012-07-31 | 571     |
| 966  | 2014-04-30 | 350     |
| 1005 | 2017-07-31 | 448     |
| 822  | 2002-04-30 | 0       |
| 879  | 2007-01-31 | 407     |

Then we merge all three dataframes to form a unified data frame with is monthly totals:

|            | sexual | violent | property |
|------------|--------|---------|----------|
| date       |        |         |          |
| 2006-01-31 | 45     | 466     | 972      |
| 2006-02-28 | 18     | 301     | 532      |
| 2006-03-31 | 6      | 114     | 215      |
| 2006-04-30 | 18     | 347     | 688      |
| 2006-05-31 | 43     | 712     | 1315     |
| ...        | ...    | ...     | ...      |
| 2020-09-30 | 5      | 382     | 710      |
| 2020-10-31 | 3      | 417     | 739      |
| 2020-11-30 | 11     | 400     | 691      |
| 2020-12-31 | 19     | 356     | 647      |
| 2021-01-31 | 3      | 66      | 76       |

Employment Data:

The employment data is reported in monthly fashion yet to crop out the Buffalo city data from the data frame few transformations must be made.

|   | Area        | Year | Month | Labor Force | Employed | Unemployed | Unemployment Rate |
|---|-------------|------|-------|-------------|----------|------------|-------------------|
| 0 | Albany City | 2021 | 1     | 46,800      | 43,100   | 3,700      | 7.9               |
| 1 | Albany City | 2020 | 12    | 47,200      | 43,500   | 3,700      | 7.8               |
| 2 | Albany City | 2020 | 11    | 47,400      | 43,800   | 3,600      | 7.7               |
| 3 | Albany City | 2020 | 10    | 47,200      | 43,500   | 3,800      | 8.0               |
| 4 | Albany City | 2020 | 9     | 47,200      | 43,200   | 3,900      | 8.4               |

the first transformation is establishing a datetime column By joining year and month columns and adding a day.

The following code was used :

```
df3=df2[['Year','Month']]
```

```
df3['day']=1
```

```
df3=pd.to_datetime(df3,yearfirst=True,errors='coerce',format='%m-%Y')
```

```
df2['Date']=df3
```

The product:

|   | Area        | Year | Month | Labor Force | Employed | Unemployed | Unemployment Rate | Date       |
|---|-------------|------|-------|-------------|----------|------------|-------------------|------------|
| 0 | Albany City | 2021 | 1     | 46,800      | 43,100   | 3,700      | 7.9               | 2021-01-01 |
| 1 | Albany City | 2020 | 12    | 47,200      | 43,500   | 3,700      | 7.8               | 2020-12-01 |
| 2 | Albany City | 2020 | 11    | 47,400      | 43,800   | 3,600      | 7.7               | 2020-11-01 |
| 3 | Albany City | 2020 | 10    | 47,200      | 43,500   | 3,800      | 8.0               | 2020-10-01 |
| 4 | Albany City | 2020 | 9     | 47,200      | 43,200   | 3,900      | 8.4               | 2020-09-01 |

We needed to transform all the column data types to the miracle data types which required to rid of commas from reported numbers then transforming the numbers to integers.

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 74423 entries, 0 to 74422
Data columns (total 6 columns):
#   Column
Non-Null Count  Dtype
---  -
0   Area
74423 non-null  object
1   Labor Force
74423 non-null  int32
2   Employed
74423 non-null  int32
3   Unemployed
74423 non-null  int32
4   Unemployment Rate
74423 non-null  float64
5   Date
74423 non-null  datetime64[ns]
dtypes: datetime64[ns](1), float64(1), int32(3), object(1)
memory usage: 2.6+ MB
```

Now that the dataframe is ready, we have to crop Buffalo out of it and merge it with the crime data frame.

Code:

```
Buff=df2[df2['Area']=='Buffalo City']
```

|      | Area         | Labor Force | Employed | Unemployed | Unemployment Rate | Date       |
|------|--------------|-------------|----------|------------|-------------------|------------|
| 6510 | Buffalo City | 109400      | 97400    | 12000      | 11.0              | 2021-01-01 |
| 6511 | Buffalo City | 110600      | 98300    | 12300      | 11.1              | 2020-12-01 |
| 6512 | Buffalo City | 110000      | 98800    | 11100      | 10.1              | 2020-11-01 |
| 6513 | Buffalo City | 110200      | 98800    | 11400      | 10.3              | 2020-10-01 |
| 6514 | Buffalo City | 110100      | 97900    | 12300      | 11.1              | 2020-09-01 |

Code :

```
final=pd.merge(df, Buff, how='left', on='date')
```

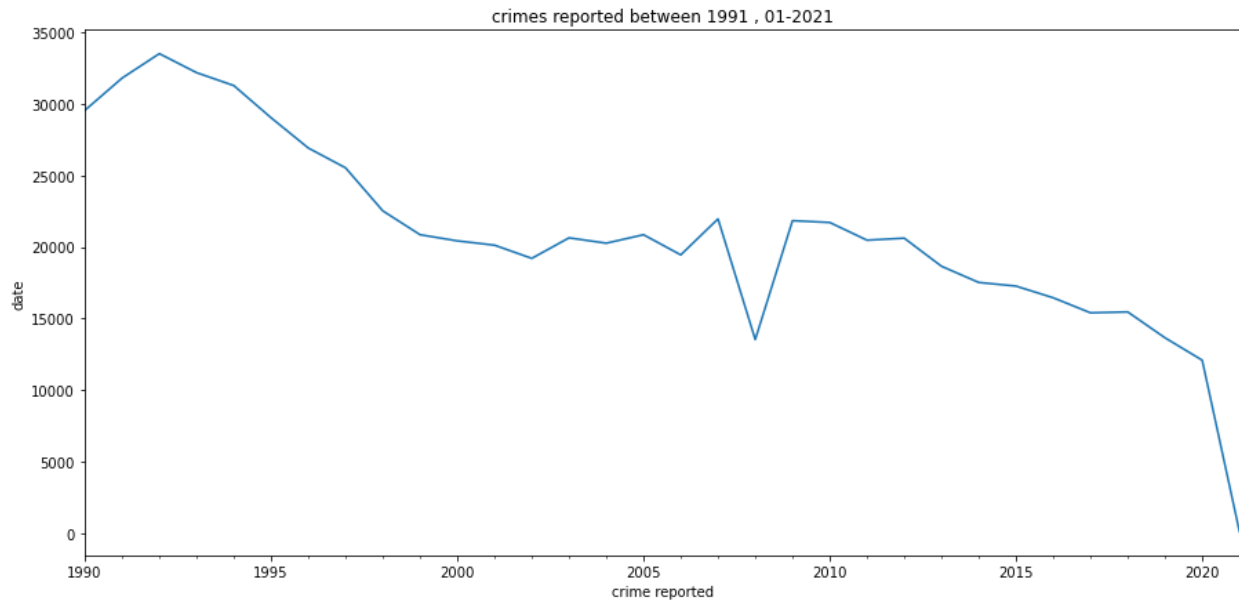

|     | sexual | violent | property | date       | Area         | Labor Force | Employed | Unemployed | Unemployment Rate |
|-----|--------|---------|----------|------------|--------------|-------------|----------|------------|-------------------|
| 108 | 30     | 373     | 919      | 2015-01-01 | Buffalo City | 110300      | 101700   | 8600       | 7.8               |
| 97  | 17     | 284     | 767      | 2014-02-01 | Buffalo City | 111400      | 101400   | 10000      | 8.9               |

| 120 | 32     | 355     | 880      | 2016-01-01 | Buffalo City | 109600      | 102500   | 7100       | 6.5               |
| 104 | 19     | 361     | 1153     | 2014-09-01 | Buffalo City | 111100      | 102600   | 8500       | 7.7               |
| 154 | 26     | 323     | 773      | 2018-11-01 | Buffalo City | 107400      | 102400   | 5000       | 4.6               |
| 172 | 3      | 326     | 614      | 2020-05-01 | Buffalo City | 109200      | 88100    | 21100      | 19.3              |
| 45  | 34     | 552     | 1415     | 2009-10-01 | Buffalo City | 121900      | 109800   | 12100      | 9.9               |
| 140 | 26     | 433     | 935      | 2017-09-01 | Buffalo City | 110600      | 103600   | 7000       | 6.3               |
| 153 | 28     | 373     | 910      | 2018-10-01 | Buffalo City | 108600      | 103600   | 5000       | 4.6               |

The data frame is now ready for the exploratory data analysis.

EDA:

Since we are trying to predict the number of crimes that are ought to be committed on a monthly basis ,we need to understand our data from that perspective .

Time series analysis heavily emphasize few points first is the trend, is our data showing any sort of trend ?

Plotting the crime data shows that crime is trending downwards, this could be attributed to many factors, therefore a correlation map it is warranted.

The correlation map shows that crime total and labor force have the highest correlation and unemployment rate has somewhat of decent correlation.

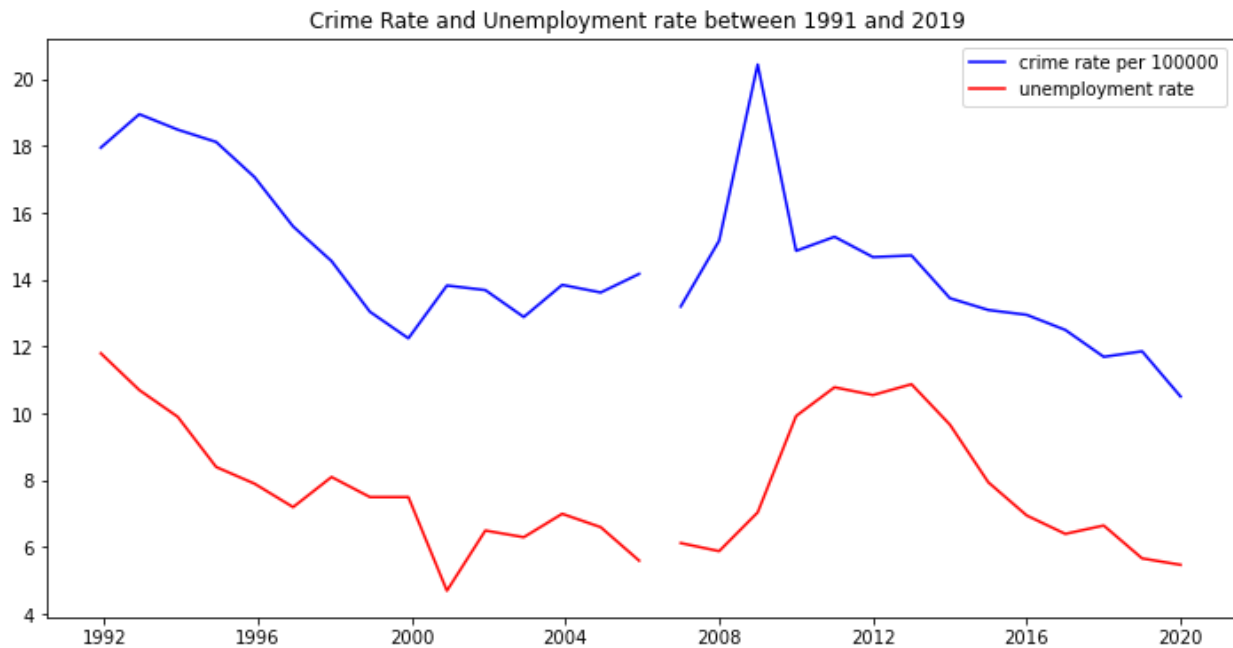

From the labor census provided by the New York State department Of Labor force we could conclude that the trend down in crimes committed is heavily influenced by their reduction of labor force and overall population using the logic less people that commit crimes results in less crimes committed.

Now that the trend is somewhat explained we need to explore the relationship between the unemployment rate and crime ,but first for us to be able to plot the unemployment rate with crime we need to transform the crime total to crime rate.

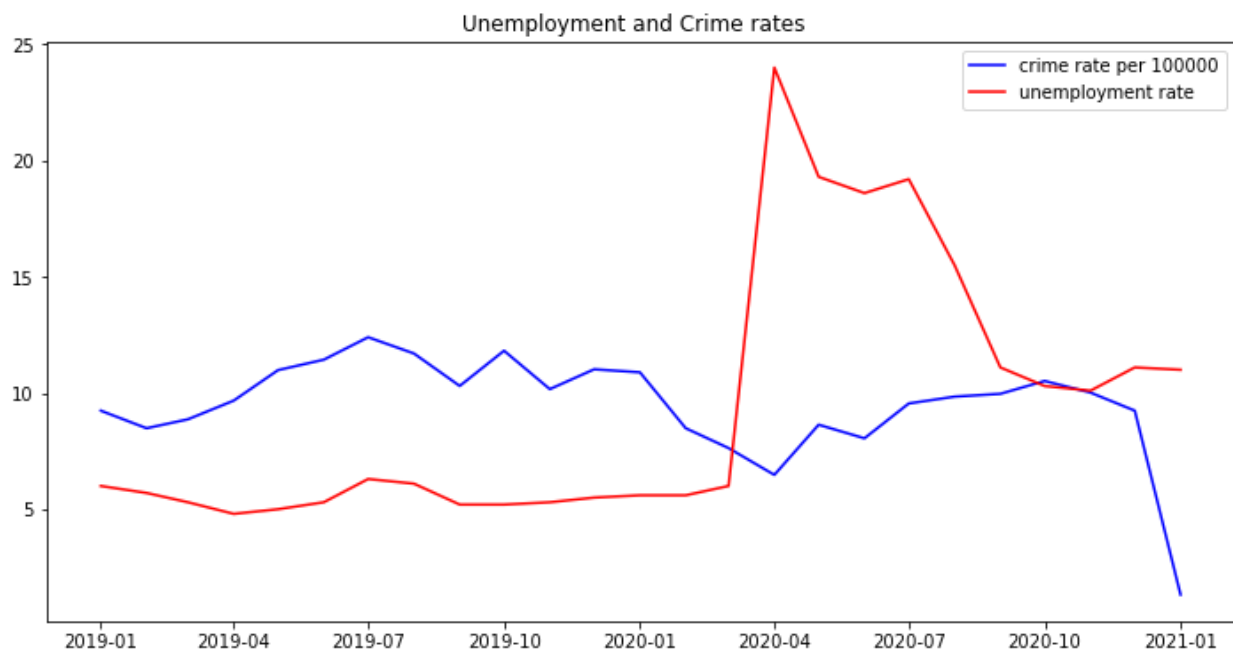

the crime rate his calculated as percentage per 100,000 , therefore we need population figures, a problem arise when trying to find monthly reported population figures since census are carried out once every 10 years , so in order to make the crime rate per 100,000 we need to make the assumption that labor force as a percentage is 50% of the population, it is highly unlikely that the labor force is 50% of the population since the labor force is calculated as the number of individuals between 16 and 65 ,yet for the purpose of data exploration we can make the exception of making an assumption about the labor force being half of the population.

Using the university of Arkansas's method and assuming that the population is likely double the labor force We derive the following equation :

$$\text{Crime rate} = ((\text{crime total} / \text{labor force} * 2) * 100,000) / 100$$

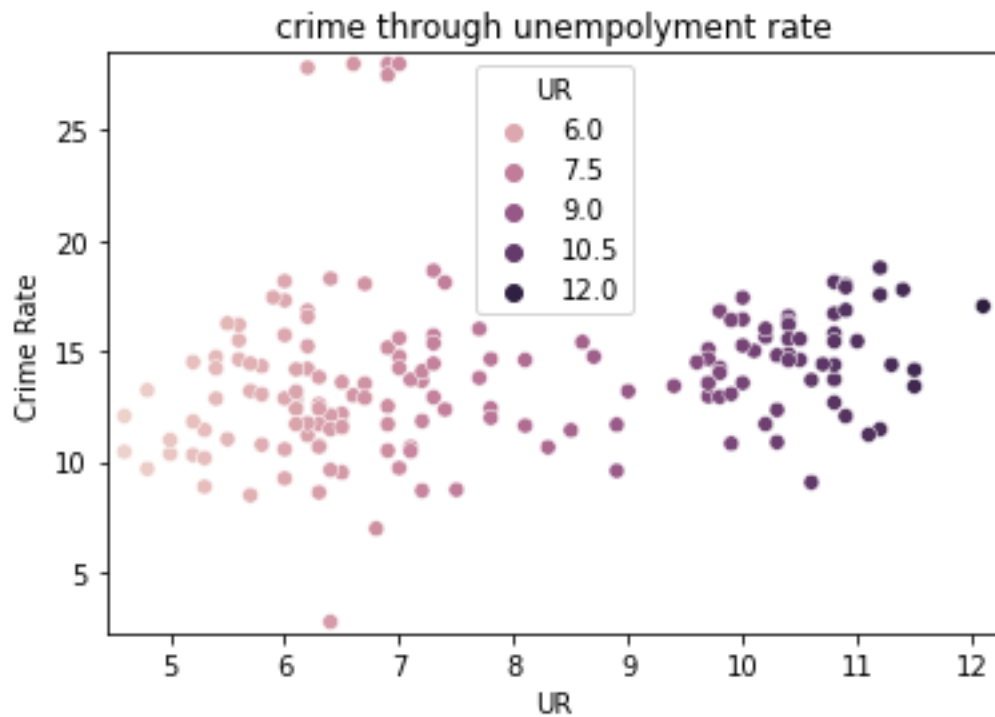

From the following plot it's fairly assumes that the correlation between the crime and unemployment is significant since they both follow the same trajectory for the past 30 years. Yet, while exploring the data an anomaly was detected which was in 2020 the unemployment rate reached up to 24% meanwhile the total crimes committed dropped significantly.

This could be justified with the advent of the coronavirus pandemic and the restrictions imposed on businesses. Such as lockdown and limited capacity, requires us to generate new exogeneous variables to justify the divergence.

To explore the crime rate's correlation with the unemployment rate we plotted a scatter plot coloring the crime rate with unemployment rates.

This scatter plot shows minimal correlation between crime rate and unemployment rate pushing us to rid of the unemployment rate as the main exogeneous variable to help predict crime.

Aside from Trend and exogeneous variables exploration time series analysis requires us to see if the variable we would like to predict has any seasonality, a simple plot of the crime rate shows that every year the crime spikes and dips indicating seasonality in the data.

#### Pre-Processing:

In the preprocessing stage we added context variables to explain a huge drop in crimes committed, the context variables are extraordinary government interventions used to stabilize the economy and provide citizens with income due to employment loss resulting of lockdowns and business restrictions.

The United States government in March 2020 passed a stimulus package that includes unemployment supplement paid to workers that lost their jobs due to the coronavirus pandemic and issued stimulus checks for the entire population.

we translated the government intervention to machine comprehensible variables that followed a machine logic of the number one indicating the existence of the variable and the number 0 indicating the absence of the variable. Note we could not include all the variables contributing to crime therefore we focused on macroeconomic changes.

Here is a snapshot of the resulting data frame:

|            | sexual | violent | property | Labor Force | Employed | Unemployed | UR  | ctotal | lockdown | e_stimulus | crime_rate |
|------------|--------|---------|----------|-------------|----------|------------|-----|--------|----------|------------|------------|
| date       |        |         |          |             |          |            |     |        |          |            |            |
| 2008-01-01 | 27     | 787     | 2592     | 120700      | 112300   | 8400       | 6.9 | 262    | 0        | 0          | 1.085336   |

#### MODELING:

Since the data is seasonal we have many options to forecast crime one of them as Arima model , Arima stands for auto regressive moving average model, this model will forecast the moving average of future crimes committed , Arima models does not forecast seasonality or include any exogenous variables , therefore if we need and accurate forecasting we need to add seasonality to the forecast that could be achieved by using Sarimax model which is seasonal other aggressive moving average (Rob J Hyndman, 2016).

As mentioned above Sarimax is based On the Arima model and requires seven parameters to be found for the model to operate correctly , the parameters are Arima order which requires three parameters P, D, Q. seasonal order of P, D, Q, S . P is the auto regression order, D is the differencing order, Q is the moving average order , S is the season order (Rob J Hyndman, 2016).

Time series analysis requires the data to be stationary, stationarity means that the data should not have any trend to it. There are many ways to achieve stationarity , one way to achieve stationarity is by shifting the data ,Shifting the data was chosen because we are dealing with consequential data meaning The number of employed could take time to affect the crime number at a later date . To test for stationarity, we can use the Adfuller test, Code:

```
def adfuller_test(data):
    result=adfuller(data)
    labels=['ADF test statistic','P-value','#lags used','Number of Observations Used']
    for value,label in zip(result,labels):
        print (label+'-'+str(value))
```

```
if result [1]<=0.05 :
```

```
    print ('strong evidence against null hypothesis (h0), reject Null hypothesis, Data is stationary')
```

```
else:
```

```
    print ('weak evidence against alternative hypothesis, time series has a unit root, indicating data is not stationary')
```

Adfuller test outputs variables such as ADF test statistic , p\_value , number of lags used , and number of observations , the most significant out of all is the p\_value which indicates if data is stationary or not , if the p\_value is higher than 0.5 the data is stationary.

Shifting the data works in the following way: subtracting the data to itself while being moved one month forward, example: crime total – (crime total +1month). Note the differencing number in which the shift was made to achieve data Stationary is a part of the model parameters (d).

Once the D parameter is found we need to find P and Q, AIC and BIC tests are mainly the ways to find such parameters, also they could be found manually using Auto Correlation and Partial Auto Correlation.

Auto correlation, Partial Auto correlation Example:

With Auto Correlation we could find out if the model an AR or MA model, and Partial Autocorrelation helps us finding P and Q. Significant values in Auto Correlation are the values not covered by the shade , if the AutoCorrelation plot shows significant lags in the beginning then trails off within the shade it means the model is an AR model , if the AutoCorrelation plot exhibits another significant lags after it dips in the non-significant zone then the model is ARMA .

AutoCorrelation code:

```
plot_acf(diff,lags=11)
```

Partial AutoCorrelation code :

```
plot_pacf(diff,lags=11)
```

For our Model we used an AIC BIC test to find the best parameters with the following code:

```
def aic_bic(p,q):
```

```
    order_aic_bic=[]
```

```
    for p in range(p):
```

```
        for q in range(q):
```

```
            model = SARIMAX(X_train, order=(p,0,q))
```

```
            results = model.fit()
```

```
            order_aic_bic.append((p,q,results.aic, results.bic))
```

```
    order_df = pd.DataFrame(order_aic_bic, columns=['p', 'q', 'AIC', 'BIC'])
```

```
    print(order_df.sort_values('AIC').head())
```

```
    print(order_df.sort_values('BIC').head())
```

the aic\_bic function returns a table of AIC and BIC test results:

|    | p | q | AIC         | BIC         |
|----|---|---|-------------|-------------|
| 19 | 2 | 5 | 1874.958986 | 1898.021401 |
| 39 | 5 | 4 | 1875.783644 | 1904.611663 |
| 26 | 3 | 5 | 1875.965290 | 1901.910507 |
| 33 | 4 | 5 | 1876.162164 | 1904.990183 |
| 40 | 5 | 5 | 1877.322247 | 1909.033068 |
|    | p | q | AIC         | BIC         |
| 5  | 0 | 5 | 1878.599296 | 1895.896107 |
| 19 | 2 | 5 | 1874.958986 | 1898.021401 |
| 8  | 1 | 1 | 1889.966374 | 1898.614780 |
| 12 | 1 | 5 | 1878.939695 | 1899.119308 |
| 18 | 2 | 4 | 1880.483898 | 1900.663511 |

As a rule of thumb when using AIC and BIC test lower AIC means better predictions and lower BIC means better training or at least that is what I learned from DataCamp course on time series analysis.

The best Parameters showing are 2 for p and 5 for q.

Now that we have all three parameters p,d,q we can test them on an Arima model using the code

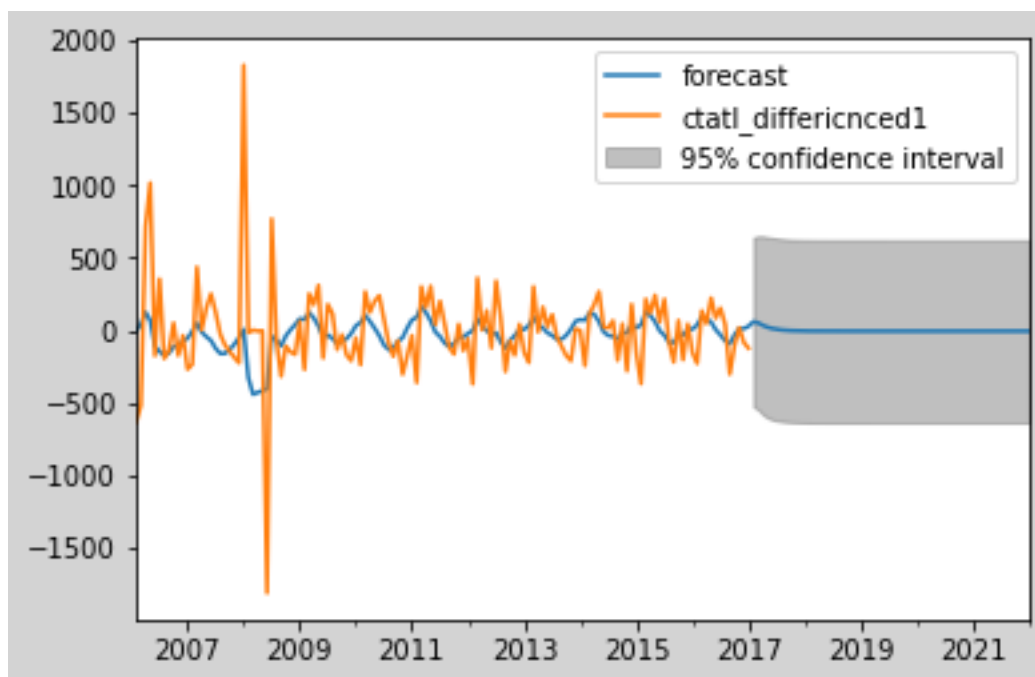

```
# we first make the train test split
X=df.ctotal
y=dfmms.drop("ctatl_differicnced1",axis=1)

y_train=y['2006-08-01':'2017-01-01']
y_test=y['2017-01-01':'2020-01-01']
X_train=X['2006-08-01':'2017-01-01']
X_test=X['2017-01-01':'2019-12-01']

model=ARMA(X_train.dropna(),order=(2,1,5))
res=model.fit()

res.plot_predict(start=0,end='2022')
```

which resulted in the following plot:

The resulting plot does not seem like the best prediction plot we need something more tangible and useable.

So far we looked for three different variables P, D, Q , now it's time to find our seasonal order for the data , there are few ways to find seasonal order, the first is using seasonal decomposition Then applying partial autocorrelation to find the significant lags.

Code:

```
fig, (ax1, ax2) = plt.subplots(2,1,figsize=(8,6))  
plot_acf(diff,lags=40,zero=False, ax=ax1)  
plot_pacf(diff,lags=40,zero=False, ax=ax2)  
plt.show()
```

the return should be close to this graph:

The auto correlation is showing significant lags at 3 ,5, 6, while PCA is showing 4,5,10,14.

SARIMAX:

To Implement SARIMAX on our variables we first must split the data to test and train data, then carry out the testing. You have seen an example of crating the split in previous code, the following the code I used to train, visualize, and test:

```
def Sarimax( endog,train_exog,test_exog,order,seasonal_order)

    mod=SARIMAX(endog,exog=train_exog,order=order,seasonal_order=seasonal_order,time_varyi
ng_regression=True,mle_regression=False)

    res=mod.fit()

    pred=res.predict(start='01-01-2017',end='01-02-2020',exog=test_exog,dynamic=True)

    results=results.join(pred)

    results.rename(columns={"predicted_mean":'Sarimax[seasonal_order]'},inplace=True)
```

for plotting results:

```
def plot(sarimax_order):

    fig = plt.figure(figsize=(12, 6))

    ax1=fig.add_subplot(111)

    ax22=fig.add_subplot(111)

    ax1.plot(results[sarimax_order],color='blue',label='Pred')

    ax1.set_title('preds vs True')

    ax22.plot(results['ctotal'],color='red',label='True ')

    plt.legend()
```

testing:

```
def mape(actual, pred):

    actual, pred = np.array(actual), np.array(pred)

    return np.mean(np.abs((actual - pred) / actual)) * 100
```

after testing a quite handful of Sarimax orders I settled on

```
SARIMAX(X_train,exog=y_train,order=(2,1,5),seasonal_order=(2,0,5,6),time_varying_regression=False
)
```

that had MAPE of 8.5%, and the residual plot was all bound between 100 to – 200 on predictions. A result that I'm willing to accept for the time being until I further develop other parts of the model.
